

# **Towards Genome Medicine: UK perspective**

Tim Hubbard, @timjph

Characterizing and Displaying Genetic Variants  
for Clinical Action Workshop

1<sup>st</sup> December 2011, Gaithersburg, US

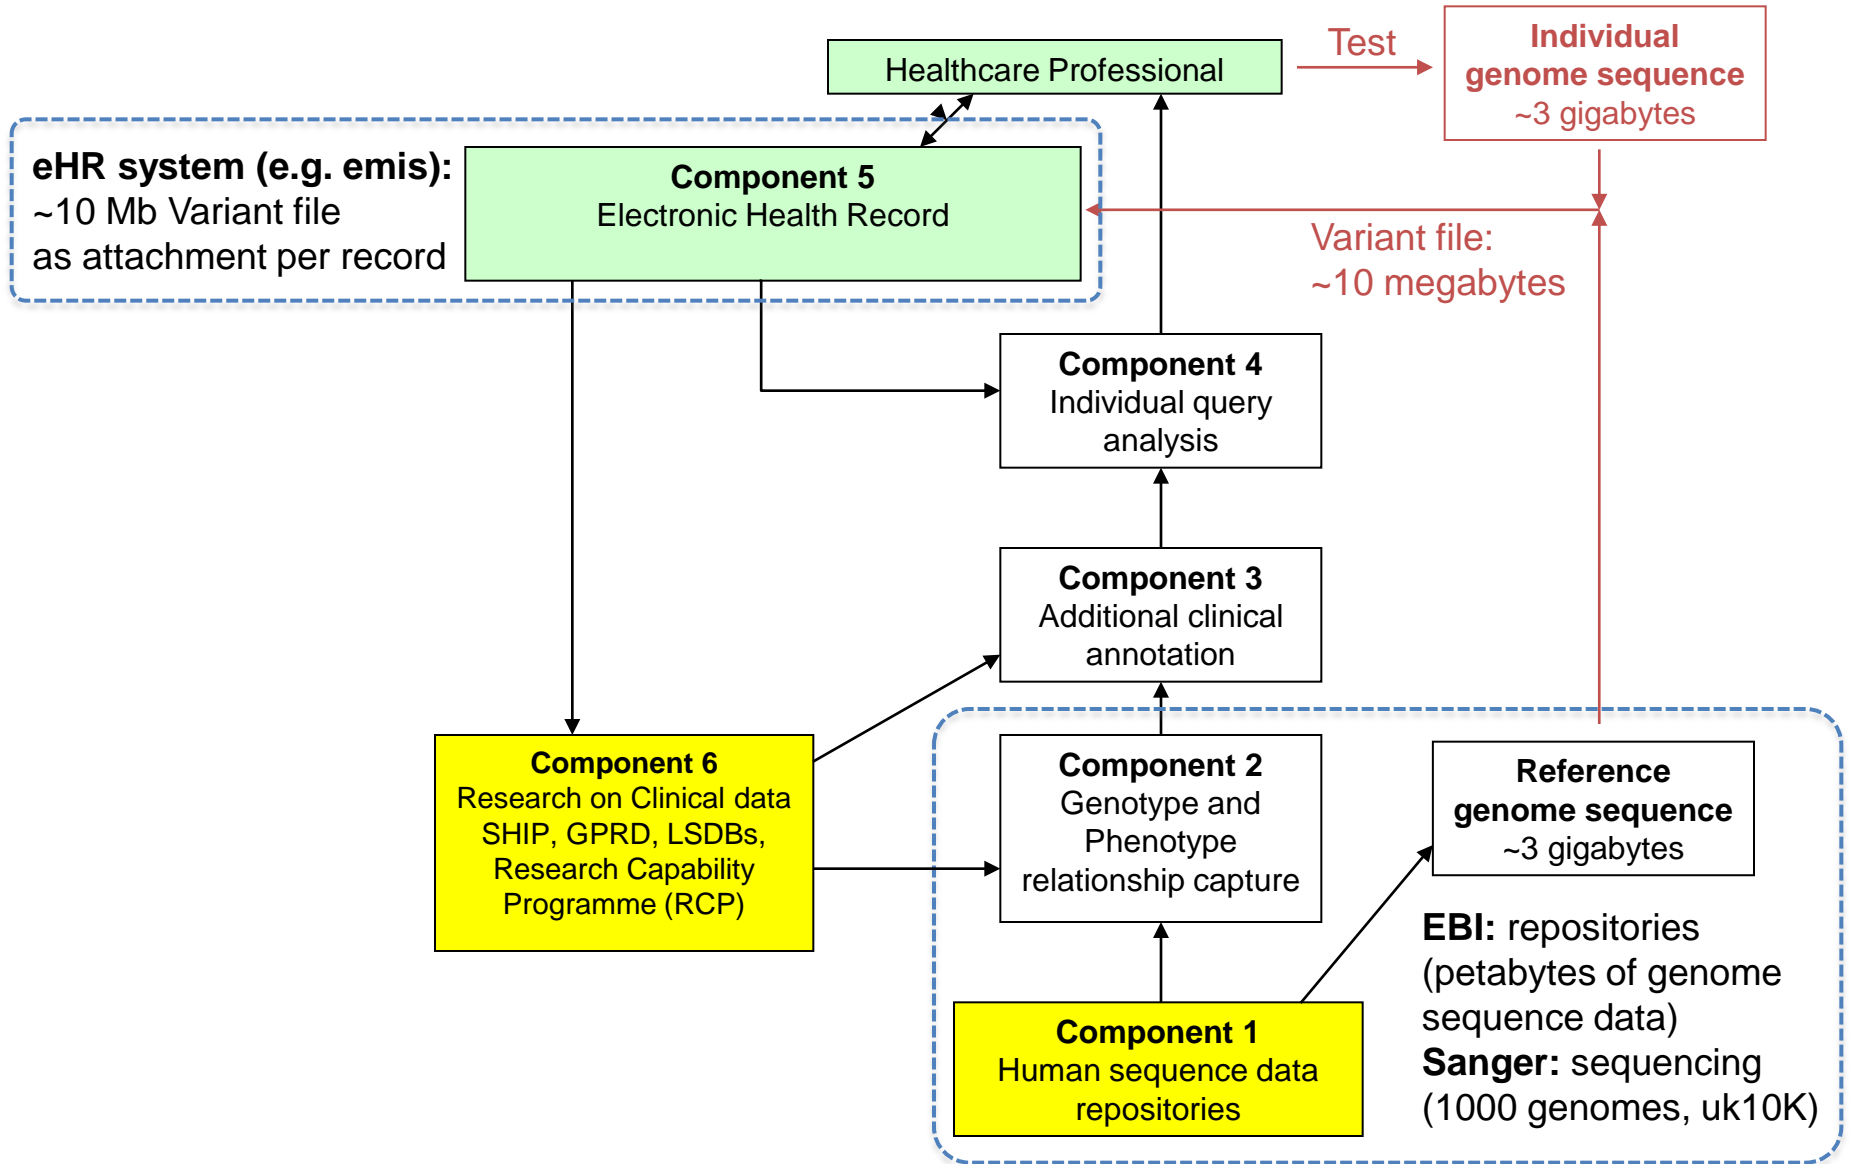

# Human Genome Sequence Costs

- Full genome sequence ~£5,000 [10/2011]
- Dropping in price 10x every 2-4 years
- Existing clinical genetic test ~£1,000 (UKGTN)
  
- Disk cost to store raw sequence ~£100
- Disk cost to store individuals variations ~10p

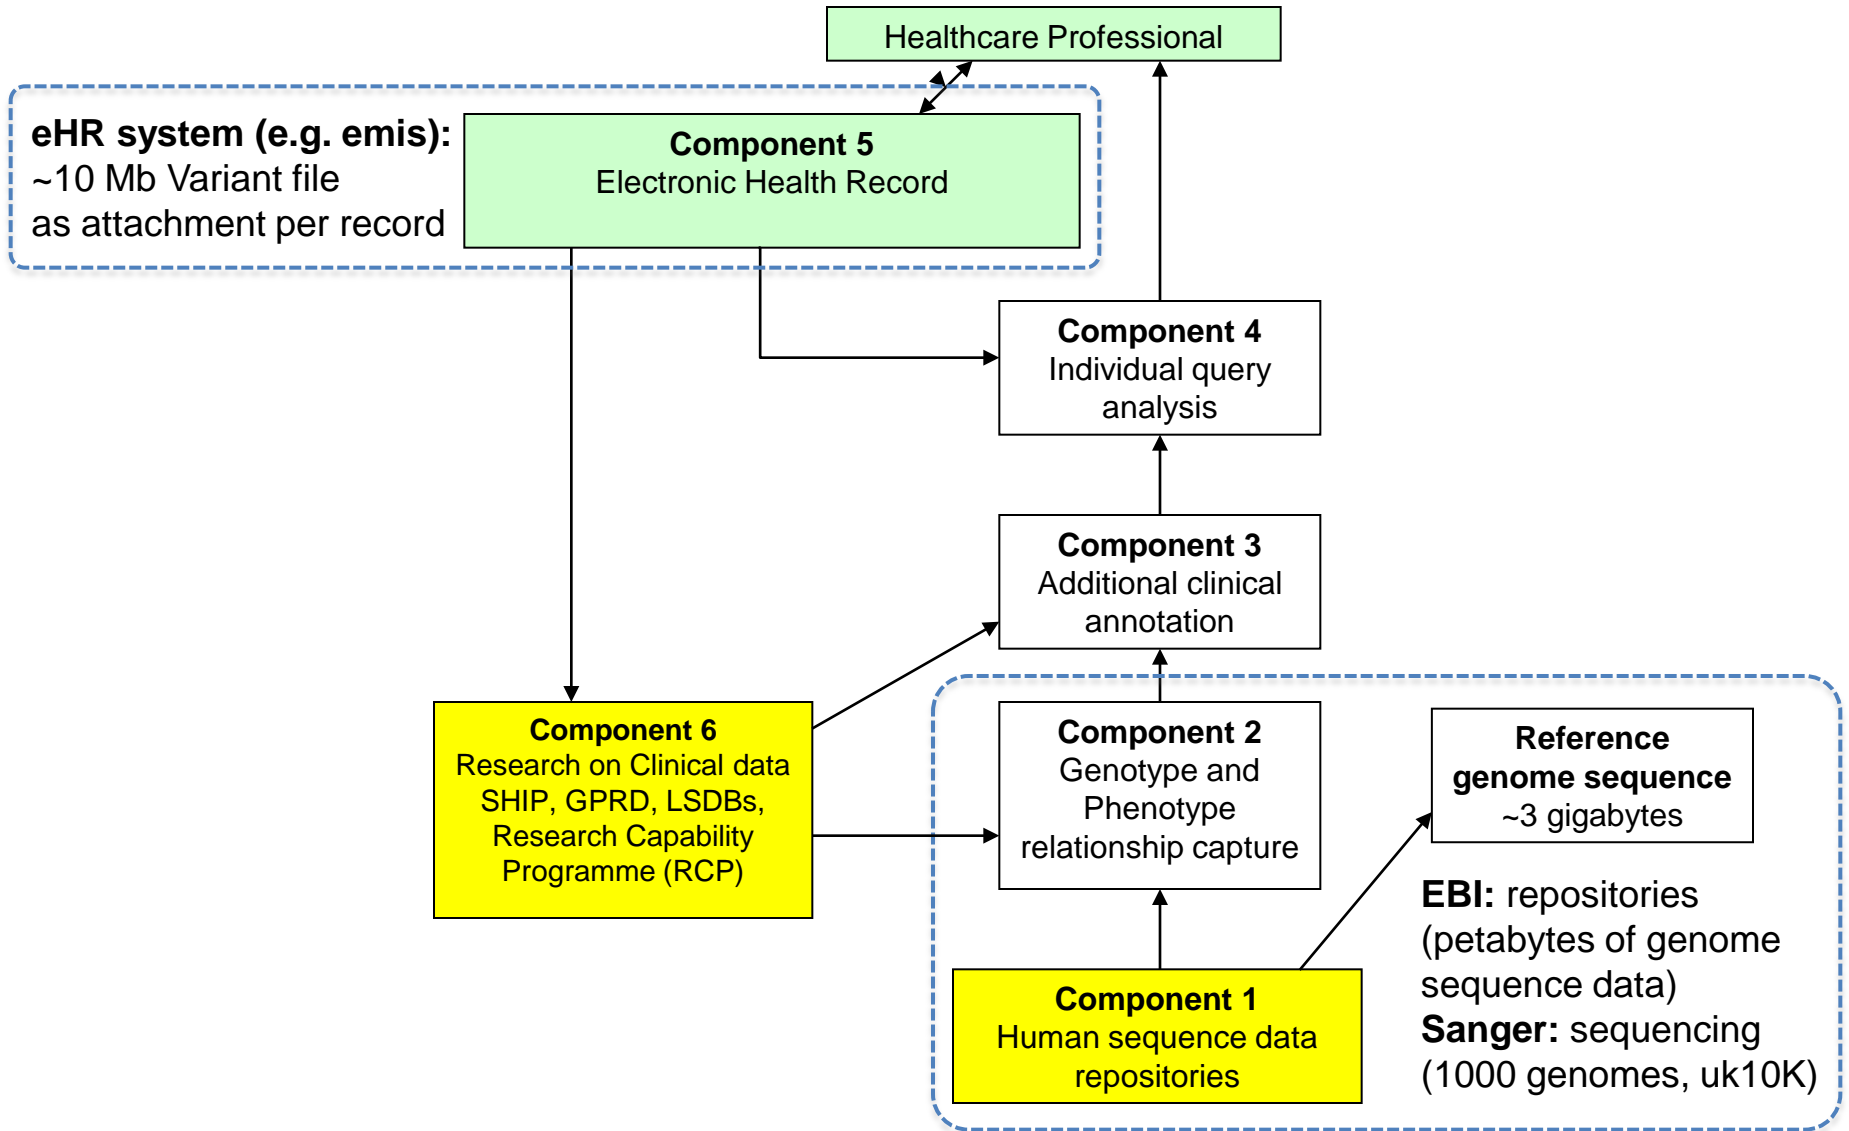

# Towards Genomic Medicine in UK

- 2006 Creation of OSCHR (Office for Strategic coordination of Health Research) to increase coordination of MRC and NHS research
- 2007 Creation of OSCHR E-health board: enabling research over health records
- 2009 House of Lords report on Genomic Medicine
- 2010 Creation of UK Government Human Genomic Strategy Group (HGSG)

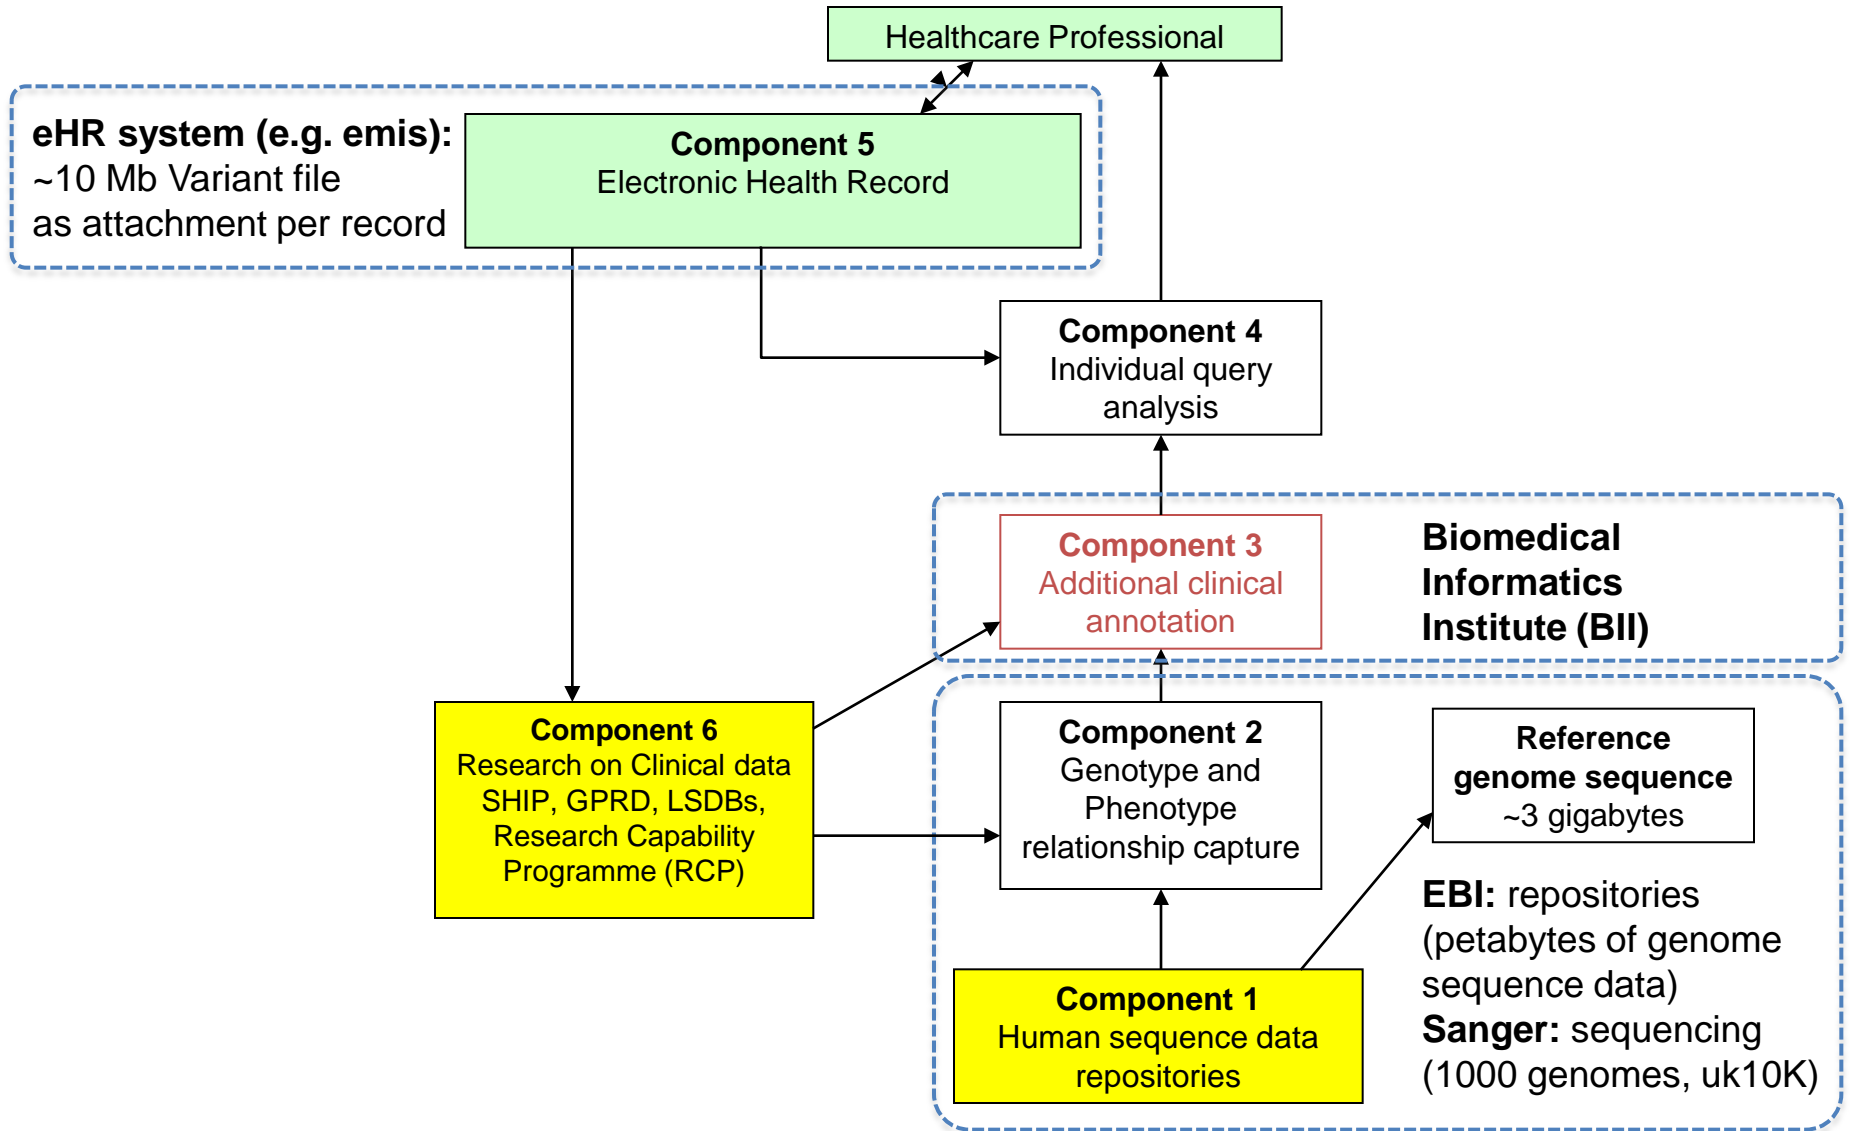

# Components for Genomic Medicine

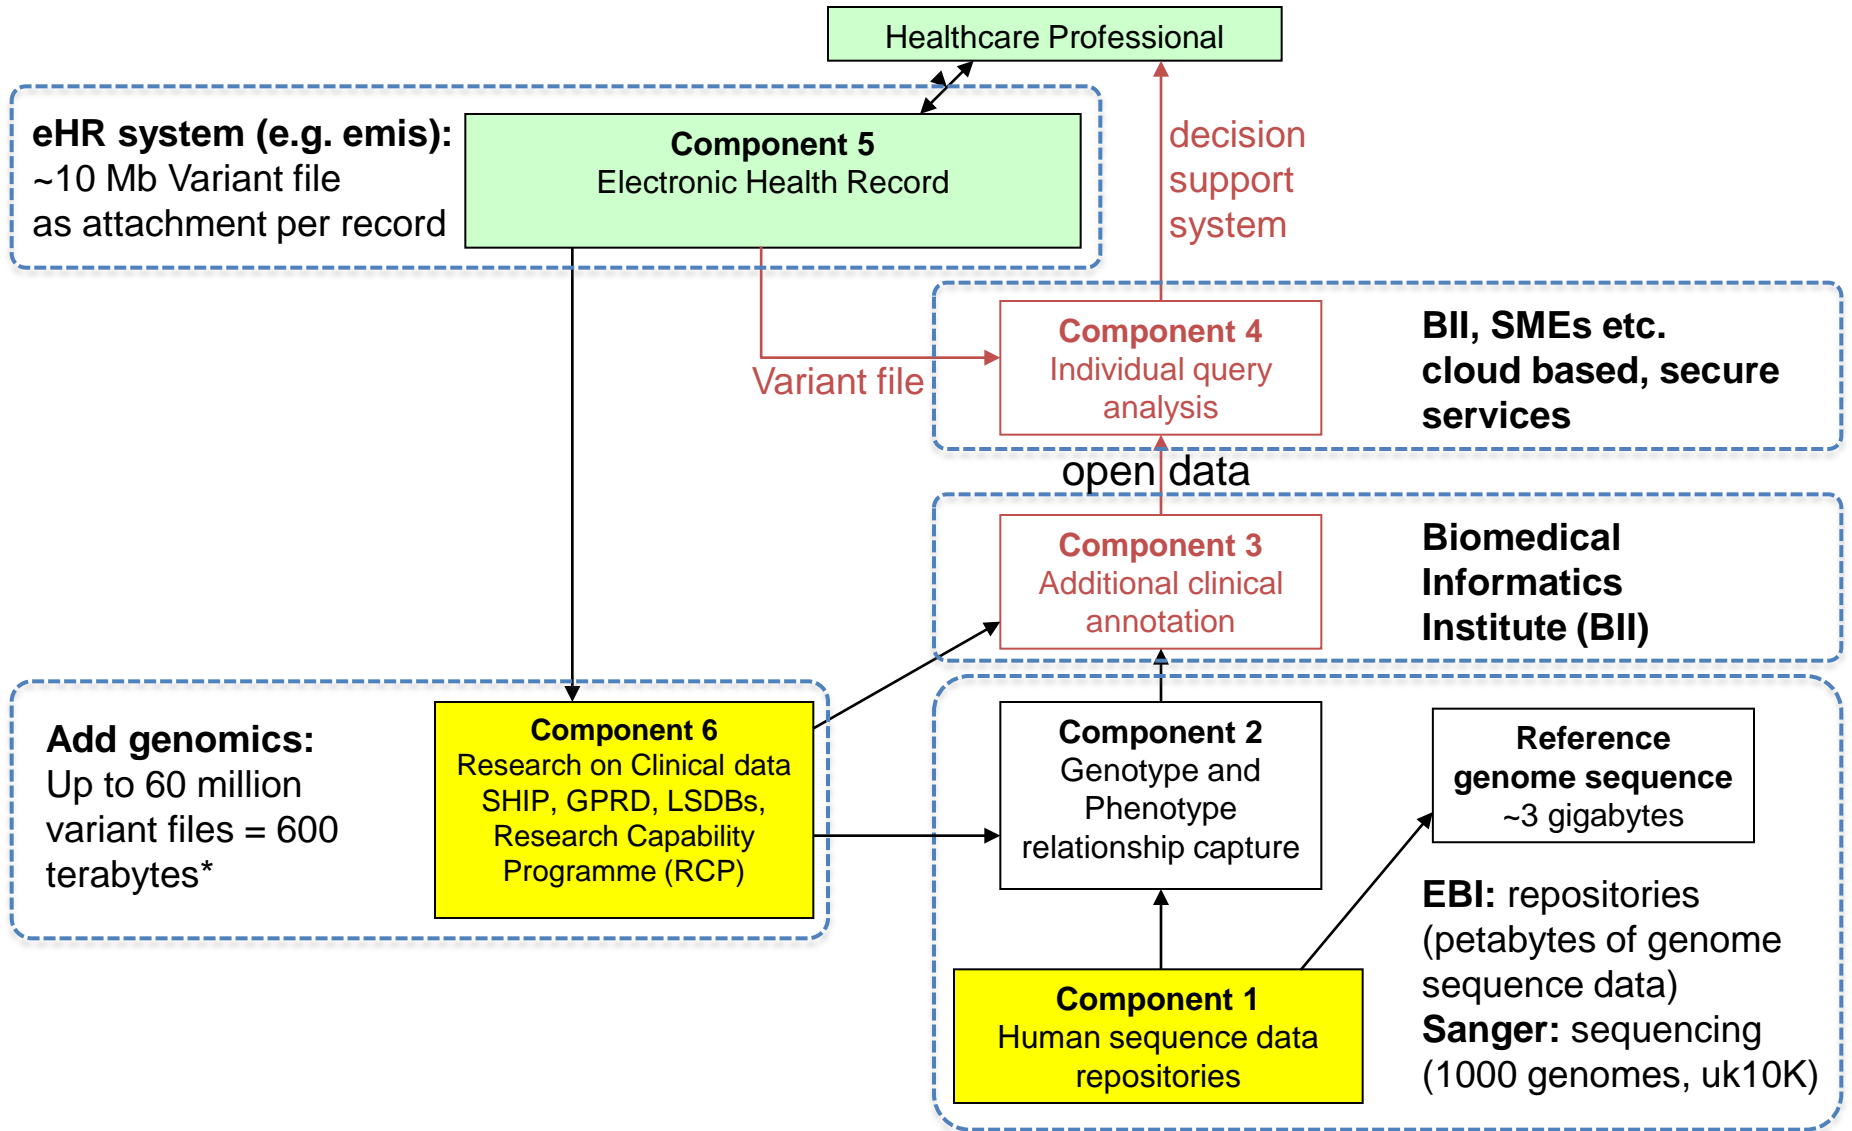

# Components for Genomic Medicine

# Components for Genomic Medicine

# ICT Components for Genomic Medicine

# Handling other genomic data

- Cancer
  - can still reduce genomes to summary files, but need to store more information: ~100Mb?
    - normal + potentially multiple cancer genome sequences (samples over time)
    - data about genome amplifications / deletions as well as genome sequence
- Pathogens / Microbiome
  - smaller genomes, more variable, many per individual, changing over time
    - reduction to summary data possible where reference genome known

# Variant / Phenotype vs Health Economics

- Research databases:
  - Millions of single nucleotide polymorphisms (SNPs) and other variants catalogued
  - Thousands of variants linked to phenotypes at gene level
- Clinical databases:
  - Small number of variants known to have clinical effect; stored in geographically distributed locus specific databases (LSDB); not systematic
  - Very limited number of variants commissioned for clinical use (pharmacogenomics, stratified medicine)

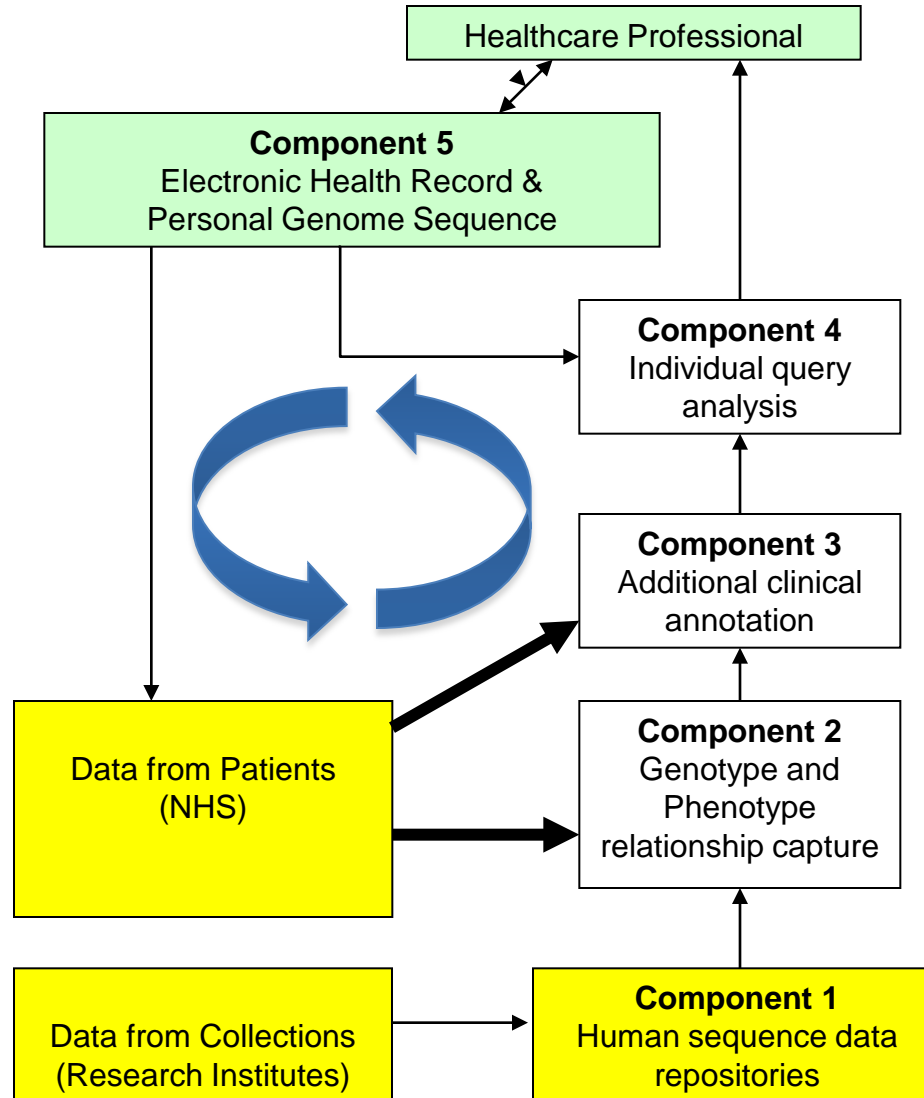

What is the potential health economic value?

# Cost benefit analysis

# Components for Genomic Medicine

# Beyond Genomic Medicine

## EU FET Flagship pilot: IT Future of Medicine (ITFoM)

The project outcomes will enable the prediction of health, disease, therapy and its effects for individual patients and through application in the clinic will change the future of medicine.

Many others for discussions

# Summary - practicality

- feasible to capture unique features of an individual genome in small variant file and easily reuse
  - store as attachment to electronic health record (eHRs) within existing systems
  - real time comparison to reference set of annotated variants via lightweight secure web services
- aggregated data stored for research will eventually be large, but still manageable
  - information in variant files will need to be reorganised to allow complex analysis; results will feed into databases of annotated variants

**Disclaimer:** The PharmGKB's clinical annotations reflect expert consensus based on clinical evidence and peer-reviewed literature available at the time they are written and are intended only to assist clinicians in decision-making and to identify questions for further research. New evidence may have emerged since the time an annotation was submitted to the PharmGKB. The annotations are limited in scope and are not applicable to interventions or diseases that are not specifically identified.

The annotations do not account for individual variations among patients, and cannot be considered inclusive of all proper methods of care or exclusive of other treatments. It remains the responsibility of the health-care provider to determine the best course of treatment for a patient. Adherence to any guideline is voluntary, with the ultimate determination regarding its application to be made solely by the clinician and the patient. PharmGKB assumes no responsibility for any injury or damage to persons or property arising out of or related to any use of the PharmGKB clinical annotations, or for any errors or omissions.

## CPIC Dosing Guideline - [azathioprine](#), [TPMT](#)

Guidelines regarding the use of pharmacogenomic tests in dosing for azathioprine, thioguanine and mercaptopurine have been published in Clinical Pharmacology and Therapeutics by the Clinical Pharmacogenetics Implementation Consortium ([CPIC](#)).

Download: [article](#) and [supplement](#)

Excerpt from the thiopurine dosing guidelines:

Thiopurines are most commonly used to treat nonmalignant conditions but are also critical anticancer agents. The approach to dosing adjustments based on TPMT status may differ depending on the clinical indication and the propensity to initiate therapy at higher vs. lower starting doses. We and others advocate testing for TPMT status prior to initiating thiopurine therapy, so that starting dosages can be adjusted accordingly.

### Recommended dosing of azathioprine by TPMT phenotype

Phenotype (Genotype)	Examples of diplotypes	Implications for azathioprine pharmacologic measures	Dosing recommendations for azathioprine	Classification of recommendations
Homozygous wild-type or normal, high activity (two functional *1 alleles)	*1/*1	Lower concentrations of TGN metabolites, higher methylTIMP, this is the "normal" pattern	Start with normal starting dose (e.g., 2-3 mg/kg/d) and adjust doses of azathioprine based on disease-specific guidelines. Allow 2 weeks to reach steady state after each dose adjustment.	Strong
Heterozygote or intermediate activity (one functional allele - *1, plus one	*1/*2, *1/*3A, *1/*3B, *1/*3C,	Moderate to high concentrations of TGN metabolites; low concentrations of	If disease treatment normally starts at the "full dose", consider starting at 30-70% of target dose (e.g., 1-1.5 mg/kg/d), and titrate based on tolerance. Allow 2-4 weeks to reach steady state after each dose adjustment.	Strong

# [www.pharmgkb.org](http://www.pharmgkb.org)

- As of 12/10/11
  - 412 variants associated with drug
  - 66 drugs with variants associated with them
- What would be the health economic benefit of using these variants across a population?
  - Currently unknown

# Summary – policy

- Clinical Services to analysis whole genomes require a database of variants
  - validated for clinical effect and health economics value
- Network of open, federated national databases is appropriate
  - nationally specific (linked to National drug lists; genetic population structure) but can build on internationally data
  - Free data access will incentivize service development (c.f. UK mapping data) and enable international data sharing
- The health value of variants in the database will increase
  - Requires research over Health records and associated genetic data

# Application areas

## 1. Personal genome sequence

- Explain rare genetic defects (now: low resolution arrays)
- Personalise drug prescription, dose (now: rarely done)
- Assessment of disease risk (now: single gene tests; entertainment)

## 2. Cancer genome sequence

- Design treatment based on exact genetic defect (now: expression microarrays / correlations)
- Watch for reoccurrence

## 3. Pathogen genome sequences

- Identifying cause of illness (now: lengthy culture)
- Tracking evolution and spread of epidemic (now: culture based)
- Treatment that takes into account personal gut flora (now: unknown)

# Starting point for Personal Genome Sequence:

- Will be as cheap to obtain and store full genome sequence as carry out any existing specific test
- Subsequent 'tests' will have negligible cost (IT costs alone) and be near instant
  - Changes health economics and practicality of 'tests' for clinical decision making

What is needed to enable this?
